

# IO-Warrior56

## Generic universal I/O Controller for USB

**Code Mercenaries**

### 1. Features

- Full speed USB interface (12MBit/sec)
- Full USB V2.0 compliant full speed device
- Full USB HID 1.1 compliance
- 50 general purpose I/O pins
- Supports IIC compatible devices with 50, 100 or 400kbit/sec
- Supports a wide range of alphanumeric and graphic LCD modules
- SPI master up to 12MBit/sec
- Drives a LED matrix up to 8x64 with a few external shift registers
- Drives a 8x8 key or switch matrix.
- Easy to use starter kit
- Software support for Mac(10.2 and up), Linux (Kernel 2.6), and Windows (2K/XP, not compatible with 98)
- No USB knowledge necessary to use
- Single +5V power supply
- Available in MLFP56 package or 100mil spaced through hole module.
- Extended temperature range: -40°C to +85°C

#### 1.1 Variants

Right now the IO-Warrior chip family is available in two low speed and one full speed variant. This data sheet describes the full speed variant IOW56. For the low speed IO-Warrior chips please refer to the separate data sheet.

#### 1.2 Custom variants

Custom adaptations are available on request.

#### 1.3 Supported OSes

W2K, WXP

98SE and ME should work but are not tested and no support available

Linux kernel 2.6 and up

MacOS X 10.2 and up

### 2. Functional overview

IO-Warrior offers a simple access to the USB. Many projects that formerly used the parallel port or some other kind of direct I/O interface today face the problem that getting simple things to work on the USB is quite complex.

With a serial or parallel port you needed only a simple circuit to control an external relay or read a single switch. With USB you need a microcontroller that handles all the protocol work to do the same thing. Several standard commands need to be supported to get a device accepted as a USB device, let alone implementing any real function.

IO-Warrior brings simplicity to the USB. The protocol is encapsulated in the IO-Warrior Chip. You only have to care about the I/O pins and have to write only a few simple lines of code to access them.

IO-Warrior also supports a range of industrial standard interfaces to simplify interfacing to certain chips or modules. These interfaces are handled internally in IO-Warrior removing the bandwidth wasting controlling of individual pins.

# IO-Warrior56

## 2.1 Product selection matrix

Type	USB Speed	I/O Pins	LCD	IIC	SPI	RC5 IR	Keys	LEDs	DIL40	SSOP48	DIL24	SOIC24	MLFP56	Module
IO-Warrior40	low	32	✓	✓			✓	8x32	✓	✓				
IO-Warrior24	low	16	✓	✓	✓	✓		8x32			✓	✓		
IO-Warrior56	full	50	✓	✓	✓		✓	8x64					coming	✓

## 2.2 Starter Kits

With the IO-Warrior Starter Kits you can make your first steps with IO-Warrior 56. A few elements on the kit allow first experiments with inputs and outputs, the bread board area provides space to test your individual circuit.

The starter kits are sold unassembled. A few minutes soldering will provide you with a working unit.

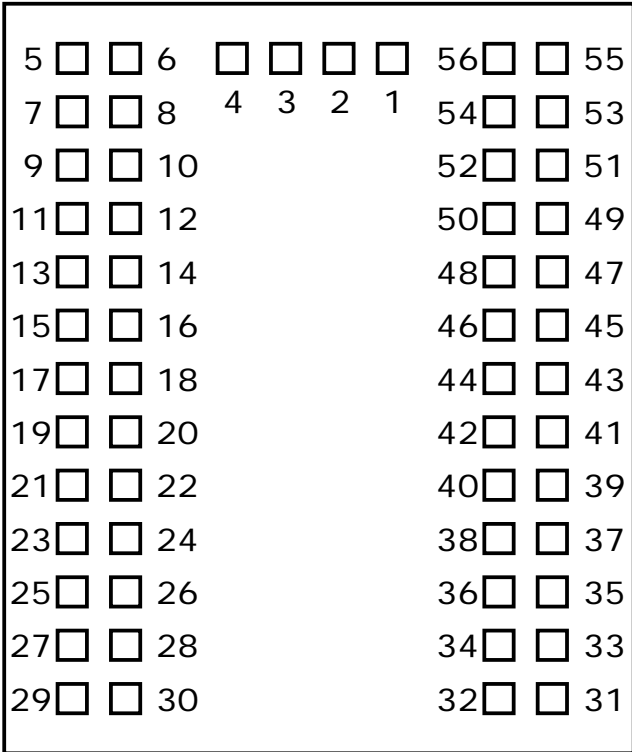

Actual components supplied with the kit may vary from those shown here.

# IO-Warrior56

## 4.1 Pin descriptions

### D+, D-

Differential data lines of USB. Put 24 $\Omega$  series resistors in these lines and connect them to the USB cable or plug, see application circuit for details. The IOW56MOD already has the series resistors.

For a PCB layout make sure to run these two signals next to each other. USB data is a differential signal that produces best signal quality and lowest RF emission if the two lines are close to each other.

### P0.0..P0.7

First I/O port of the chip. These pins correspond with the lowest 8 bits of the input or output (bits 0..7).

### P1.0..P1.7

Second I/O Port. Corresponds to the bits 8..15. P1.0 and P1.1 are used during production of the IOW56. After power up and during the internal start up process of IOW56 these two pins can change their status a couple times. Take this into account when connecting external circuits.

### P2.0..P2.7

Third I/O Port. Corresponds to the bits 16..23.

### P3.0..P3.7

Fourth I/O Port. Corresponds to the bits 24..31.

### P4.0..P4.7

Fifth I/O Port. Corresponds to the bits 32..39.

### P5.0..P5.7

Sixth I/O Port. Corresponds to the bits 40..47.

### P6.0, P6.7

Seventh I/O Port. Corresponds to the bits 48 and 55. This port has only two pins. Always write the unused bits as "1".

### GND

Power supply ground.

### Vcc

Supply voltage.

A 100nF ceramic capacitor is required to be connected directly to each pair of the power supply pins. The IOW56MOD already has the capacitors. The MLFP56 package has a center ground pad that must be connected to ground (Vss).

## 4.2 Special mode pin functions

IO-Warrior56 supports various higher level functions including IIC, SPI, LED matrix, key matrix, and driving various LCD modules. Handling IIC via the normal generic I/O would be very slow as each edge of data and clock would have to be transmitted separately. At a rate of 1000 such transactions per second (which is the maximum IO-Warrior56 is allowed by USB specifications) the maximum bit rate and throughput would be around 250 bits/sec.

To make IIC and other devices usable IO-Warrior implements the special mode functions. By handling the IIC inside IO-Warrior the actual data rate is approaching the theoretical maximum.

When any of the special mode functions is activated some pins will no longer respond as generic I/O pins but are under control of the activated special mode function.

### 4.2.1 IIC Mode pins

IO-Warrior56 can act as an IIC master with 50, 100, or 400kbit/sec data rate. Multi-Master mode is not supported by IO-Warrior, it has to be the only master on the IIC.

IO-Warrior56 supports clock stretching handshake with slaves that need throttling of the data flow.

The following pins get reassigned when the IIC function is enabled:

Function	IOW56
SCL	P1.7
SDA	P1.5

These pins will no longer be affected by the data sent via the normal port setting command. Both pins have internal pull up resistors and can be connected direct to IIC compatible chips.

# IO-Warrior56

## 4.2.2 LCD Mode pins

IO-Warrior56 has support for controlling LCD modules with a wide range of controllers. Refer to Application Note 5: "Controlling LCDs with IO-Warrior" for more information on compatible modules and how to use them.

The following pins get reassigned when the LCD function is enabled:

Function	IOW56
/On	P4.0
RS	P4.1
R/W/WE	P4.2
E/RE	P4.3
E2/RES	P4.4
Data0	P3.0
Data1	P3.1
Data2	P3.2
Data3	P3.3
Data4	P3.4
Data5	P3.5
Data6	P3.6
Data7	P3.7

When the LCD function is enabled these pins will no longer be affected by the normal port setting command.

/On should be used to enable power supply to LCD modules that have high current demand or backlighting. The /On signal is low when the LCD function is enabled, it does go high when IO-Warrior enters suspend mode or when the LCD function is disabled.

By default the following pins should be used for controlling the CS lines of graphic displays with multiple controller chips:

P4.5 - CS1

P4.6 - CS2

Since the polarity of the CS signals varies between LCD modules we decided not to handle them in the special mode function.

## 4.2.3 SPI Mode Pins

IO-Warrior56 supports a hardware SPI master interface. It can communicate with SPI slave devices with a data clock speed of up to 12MHz. Actual data throughput depends on a number of factors, including the size of the data packets that are transmitted. Possible peak rates are around 62,000 bytes/sec.

The following pins get reassigned when the SPI function is enabled:

Function	IOW56
/DRDY	P5.3
/SS	P5.1
MOSI	P5.2
MISO	P5.4
SCK	P5.0

When the SPI function is enabled these pins will no longer be affected by the normal port setting command. The pins have internal pull up resistors.

## 4.2.4 LED Matrix Mode Pins

IO-Warrior supports driving a LED matrix with up to 8x64 LEDs.

Function	IOW56
/OE	P1.3
Strb	P1.2
Clk	P1.1
Data	P1.0

When the LED Matrix function is enabled these pins will no longer be affected by the normal port setting command.

/OE is driven high when IO-Warrior enters the suspend mode. The external driver should then disable to stay within the USB power limits for suspend mode.

For more details on how to control a LED matrix please refer to the separate application note.

# IO-Warrior56

## 4.2.5 Switch Matrix Mode Pins

IO-Warrior supports scanning of a 8x8 matrix of keys or switches. When this function is enabled P0.0..7 will turn off their internal pull up resistors and will be used as the Y lines that are periodically driven to Gnd voltage level. P2.0..7 will serve as the X matrix inputs, they will keep their internal pull up resistors active so a closed switch in the matrix will pull down the X line when the corresponding Y line is driven low.

To allow more than two switches to be closed at the same time and still be able to faultlessly detect which of the matrix points are closed it is necessary to insert a diode in series with every key or switch in the matrix. The kathodes of the diodes have to be connected to the Y lines (P0.0..7).

The following pins get reassigned when the key mode is enabled:

Function	IOW56
X0	P2.0
X1	P2.1
X2	P2.2
X3	P2.3
X4	P2.4
X5	P2.5
X6	P2.6
X7	P2.7
Y0	P0.0
Y1	P0.1
Y2	P0.2
Y3	P0.3
Y4	P0.4
Y5	P0.5
Y6	P0.6
Y7	P0.7

The matrix is scanned every 4msec. Debounce time is 16msec.

When IO-Warrior enters the suspend mode the X and Y lines will be pulled high by internal pull up resistors. Closing a switch/key does not wake the IO-Warrior.

# IO-Warrior56

## 5. Device Operation

Due to the fact that all current operating systems offer an especially easy access to devices in the HID class, IO-Warrior was designed as a generic HID device. While this does not exactly fit the device it makes using it a lot easier.

By identifying as a generic HID class device IO-Warrior avoids being controlled by any of the higher level system drivers, which makes it possible to access IO-Warrior from application level.

### 5.1 Accessing IO-Warrior

A common misconception with people new to the USB is that they think they can "talk to the USB port". The truth is that you do that as likely as you are going to directly talk to your Ethernet port or PCI bus.

Communication on the USB is always with a specific device attached to the USB. The USB itself is only the medium through which you communicate.

To get access to a certain device you have to look for the VendorID and ProductID of that device. The specific mechanisms for doing so depend on the individual operating system.

For details refer to our sample code.

### 5.2 IO-Warrior communication

IO-Warrior56 has five USB endpoints. Endpoints are like virtual communication ports into or out of the device.

An endpoint can be assigned to an interface. Interfaces are like virtual devices or subsystems within a device. IO-Warrior uses interface 0 to talk to the pins directly and interface 1 to talk to the special mode functions.

Endpoint 0 is a standard endpoint that is present on all USB devices. It does use the control transfer mode and is used by the system to get information about the device and to configure the device.

Endpoint zero can also be used to send data to the devices functions. The low speed IO-Warrior chips use Endpoint zero for output data, IO-Warrior56 has dedicated Endpoints for the output data to achieve a higher performance.

For input data IO-Warrior is using endpoint 1 as an interrupt-in endpoint. Interrupt in this case is a bit misleading. For USB interrupt means that data is sent when there is new data available. The host computer is periodically asking the device for new data. The device itself can not initiate the data transfer. IO-Warrior sends a new report any time it

detects a change to the input pin status.

Output data to the I/O pins is sent to Endpoint 2 which is also an interrupt type endpoint. A seven byte report directly sets the status of the port pins.

Special mode functions receive their commands via Endpoint 4, also interrupt mode. The report size for the special mode functions is 63 bytes plus the report ID. This enables a single IOW56 special mode command to transport ten times more data than on the low speed IO-Warrior chips.

Reactions to commands to the special mode functions are sent via endpoint 3, also in interrupt transfer mode.

Since IO-Warrior56 uses interrupt out endpoints it can not be used with Win98.

### 5.3 IO-Warrior input behaviour

IO-Warrior checks the status of all pins once every millisecond. If it detects a change from the last status a new report via endpoint 1 is issued. Pins which are currently used by a special mode function are not checked. Reports are sent to the computer in 1msec intervals.

### 5.4 IO-Warrior output behaviour

Upon receiving the report IO-Warrior writes the new data to the output pins in groups of eight pins each. Pins 0.0 to 0.7 get the new data first, then 1.0 to 1.7, 2.0 to 2.7, and last 6.0/ 6.7.

The time between the individual ports is about 1µsec.

### 5.5 Using pins as inputs or outputs

All I/O pins on IO-Warrior can be used as input or output pins.

All pins act as inputs all of the time. When receiving an input report from IO-Warrior you always get the current status on all pins except for those currently used by special mode functions..

Writing a 0 as output value to any pin causes it to drive the pin low with an open drain driver. Usually this will result in this pin being read as a zero input as well, unless so much current has to be drained by the pin that the voltage at it gets above the threshold level.

Writing a 1 to a pin causes the open drain driver to be turned off. The pin will be pulled high by an internal pull up resistor. Now the pin acts either as an output with a high level, or can be used as an input.

# IO-Warrior56

## 5.6 Power supply

USB does allow a device to be "Bus Powered". This means the device does get its power off the USB port. To avoid overloading on the USB ports devices need to advertise their power requirements. There are two power classes for devices: Low power and high power. Low power devices may draw up to 100mA off the USB, high power devices up to 500mA.

Likewise there are high power and low power ports. Usually high power ports are those on the motherboard and on hubs with external power supply or hubs in a monitor. Low power ports are typically on hubs that get their power off the USB, like hubs in keyboards.

If the system decides that there is not sufficient power to supply a high power device that device does not get enabled.

IO-Warrior can operate either as a high power or low power device. Pulling the P6.0 pin high or low at reset sets the desired power rating.

This allows to configure IO-Warrior optimally for supporting external circuits.

## 5.7 Using external power

If an external power source is used to supply power for an IO-Warrior based circuit there are two options.

The IO-Warrior can be powered from the USB and only the external circuit gets its power off an external source. If this is a feasible design option it should be used. An I/O pin may be used to check the presence of the external power so any controlling application knows if the device is in a working configuration.

The second option is to also power IO-Warrior from an external source. This is not the recommended option since IO-Warrior assumes that the USB is active if it has power. In this case set the current request of IO-Warrior to 100mA

## 5.8 Suspend

All devices on the USB port need to support the suspended state. When the host computer stops to periodically access the USB, like when it goes to sleep, all devices need to enter the suspended state and drop their power draw to less than 500µA for low power devices or less than 2.5mA for high power devices.

When entering suspended state IO-Warrior pulls all pins high. Care must be taken in designing external circuits so that they will draw no more than the allowed suspend power rating while all

pins of IO-Warrior are high.

## 5.9 Remote Wakeup

IO-Warrior chips support the remote wakeup feature. They are able to wake the host computer from sleep state if the host operating system has enabled this feature.

Remote wakeup is initiated by IO-Warrior56 if any pin changes its state while the chip is in suspended state.

## 5.10 Special mode I/O

To enable IO-Warrior to talk to devices that have more complex demands it has the special mode functions. When any of these functions is enabled some pins of IO-Warrior turn into special function pins.

Talking to the special mode functions is handled via the USB interface 1, which is also configured as generic HID compliant.

Commands to the functions are sent as interrupt out reports via endpoint 4. Replies from the functions are returned as interrupt in reports via endpoint 3.

To talk to the various functions and to handle different requests to them ReportIDs are used which enable multiple functions to use the same endpoint. All reports to and from special mode interfaces are always 64 bytes long, including the ReportID.

The following chapters describe the individual special mode functions.

### 5.10.1 IIC Special mode function

The IIC function is enabled and disabled by sending a report with the following structure with ReportID=1 to interface 1:

ReportID	1	2	3	4	...	62	63
\$01 out	enable	speed	\$00	\$00	\$00	\$00	\$00

"enable"=\$01 enables the IIC function, \$00 disables it. Other values are reserved for future use. Upon enabling IIC the SDA and SCL pins are pulled high and are no longer under control of interface 0. Disabling IIC does return the pins under control of interface 0 and pulls them high initially.

"speed" selects the IIC clock speed.

0 = 100kHz

1 = 400kHz

2 = 50kHz

# IO-Warrior56

A write request to the IIC is send with ReportID=2 and has the following format:

ReportID	1	2	3	4	...	62	63
\$02 out	flags	data	data	data	data	data	data

flags contains the following bits:

- 7 - Generate Start
- 6 - Generate Stop
- 5 - data count MSB
- 4 - data count
- 3 - data count
- 2 - data count
- 1 - data count
- 0 - data count LSB

If bit 7 - "Generate Start" is set a start signal (SDA falling edge while SCL is high) is generated on the IIC prior to sending out the first data byte.

Bit 6 - "Generate Stop" causes a stop signal (SDA goes high while SCL is high) to be generated after sending the last valid data byte of this report.

"data count" gives the number of valid data bytes in the report. The number may range from 1 to 62, higher values cause the report to be ignored.

To do write transactions that are longer than 62 bytes, send the first report with just the "Generate Start" bit set, then send additional reports with neither bit 6 or 7 set until the last report is send which has the "Generate Stop" bit set.

Clock stretching by the slave to slow down data transfer is supported by IO-Warrior56.

Any write transactions are acknowledged by a report via interrupt-in endpoint 3:

ReportID	1	2	3	4	...	62	63
\$02 in	flags	\$00	\$00	\$00	\$00	\$00	\$00

flags contains the following bits:

- 7 - Error bit, 1=error
- 6 - unused, zero
- 5 - data count MSB
- 4 - data count
- 3 - data count
- 2 - data count
- 1 - data count
- 0 - data count LSB

"data count" indicates the last byte that was successfully transfered and acknowledged by the slave (if any). An error is indicated when the slave does not acknowledge a transfer.

Reading data off the IIC is initiated with a ReportID=3. The initiating report has the following format:

ReportID	1	2	3	4	...	62	63
\$03 out	count	command	\$00	\$00	\$00	\$00	\$00

"command" holds the command byte to be send to the IIC. "count" is the number of bytes that should be read off the IIC after sending the command byte, values 0 to 255 are valid, 0 reads 256 bytes.

A start signal is automatically generated before sending the command byte and a stop is generated after the last data byte is received.

Data is returned in input reports with ID=3 via endpoint 3. The data is returned in chunks of up to 62 bytes each with an error flag and byte count. Multiple reports may be returned in reaction to a read request:

ReportID	1	2	3	4	...	62	63
\$03 in	flags	data	data	data	data	data	data

flags contains the following bits:

- 7 - error, set if slave does not ack command byte
- 6 - unused, zero
- 5 - data count MSB
- 4 - data count
- 3 - data count
- 2 - data count
- 1 - data count
- 0 - data count LSB

Should the IIC slave fail to acknowledge the command byte the error flag will be set and the transaction aborted. IIC does not have an error condition during the actual reading of data after the command byte was sent.

Clock stretching by the slave to slow down data transfer is supported by IO-Warrior56.

# IO-Warrior56

## 5.10.2 LCD Special mode function

The LCD special mode function supports a wide range of alphanumeric and graphic LCD modules. The LCD function is enabled by sending an output report with ID 4 to the USB interface 1:

ReportID	1	2	3	4	...	62	63
\$04 out	enable	mode	\$00	\$00	\$00	\$00	\$00

enable = \$00 disables the LCD function.  
enable = \$01 enables the LCD function, other values are reserved.

"mode" contains a number of bits that determine the behaviour of the LCD interface:

- 7 - unused, zero
- 6 - unused, zero
- 5 - unused, zero
- 4 - LC7981
- 3 - T6963
- 2 - No44780Busy
- 1 - Reset
- 0 - Dual44780

"Dual44780" enables the second E signal to control modules with two HD44780 controllers on them.

"No44780Busy" must be set for controllers that don't have the busy flag in bit 7 of register 0 like the HD44780 or KS0108 controllers. Setting this flag does disable checking for the busy flag in bit 7 of the LCD register 0.

"Reset" enables the /RES pin. Upon issuing the enable report with this bit set the LCD function will pull the /RES pin low for approximately 2µsec before it is released to high again.

"T6963" switches to a mode compatible with the T6963C controllers. Make sure to also set the "No44780Busy" bit. The T6963 specific busy flags are checked in this mode. The T6963C is the only controller for which IOW56 implements the 8080 bus protocol.

"LC7981" switches to a mode compatible with the LC7981 and HD61830 controllers. Make sure to also set the "No44780Busy" bit. The LC7981 specific busy flag is checked in this mode.

Upon enabling the LCD function the Pins are put under control of the LCD function and can no longer be controlled by interface 0. The /On pin is pulled low when the LCD function is enabled, it will go high when the IO-Warrior

enters suspend state.

To write data to the connected LCD module an output report with ReportID 5 is written with the following format:

ReportID	1	2	3	4	...	62	63
\$05 out	flags	data	data	data	data	data	data

"flags" contains the following bits:

- 7 - RS, Register Select bit
- 6 - Select Special
- 5 - data count MSB
- 4 - data count
- 3 - data count
- 2 - data count
- 1 - data count
- 0 - data count LSB

The status of the "RS" bit is used to set the RS or A0 line to the LCD module.

With "data count" the number of bytes to be written is specified. IO-Warrior will write up to 62 data bytes to the register specified by the "RS" bit. If the "No44780Busy" flag has not been set the Busy bit of the LCD module is automatically checked and data written only when the LCD module is ready to accept it.

When in "Dual44780" mode the "Select Special" bit selects which of the E lines is used for this request. "Select Special" = 0 uses E1, "Select Special" = 1 uses E2.

In T6963 mode the "Select Special" bit selects if the normal busy flag or the auto mode busy flag should be checked. "Select Special" = 0 checks STA0, 1 before writing to the LCD, "Select Special" = 1 checks STA3.

To read data from the LCD module an output report with ID 6 is sent to interface 1:

ReportID	1	2	3	4	...	62	63
\$06 out	flags	\$00	\$00	\$00	\$00	\$00	\$00

"flags" contains the following bits:

- 7 - RS, Register Select bit
- 6 - Select special
- 5 - data count MSB
- 4 - data count
- 3 - data count
- 2 - data count
- 1 - data count
- 0 - data count LSB

# IO-Warrior56

"RS" specifies which register is to be accessed. "data count" sets the number of bytes to be read off the LCD.

When in "Dual44780" mode the "Select Special" bit selects which of the E lines is used for this request. "Select Special" = 0 uses E1, "Select Special" = 1 uses E2.

In "T6963" mode the "Select Special" bit selects if the normal busy flag or the auto mode busy flag should be checked. "Select Special" = 0 checks STA0, 1 before writing to the LCD, "Select Special" = 1 checks STA2.

Up to 63 bytes can be read with one request. The data read from the LCD module is returned in input reports with ID 6:

ReportID	1	2	3	4	...	62	63
\$06 in	count	data	data	data	data	data	data

"count" specifies the number of bytes returned in this report. If more than 62 bytes are requested the data will be returned in multiple reports.

Following is a list of the LCD controllers that have by now been tested with IOW56 and the mode byte that is used for them. Additional chip types will be added when tested.

Chip	mode	Remarks
HD44780	\$00 / \$01	mode = \$01 for dual chip
ST7920	\$00	
HD61202 KS0108 S6B0108	\$02	May have two chips, which means two CS lines, either polarity
S1D15xxx SED152x AX1520 NJU6450	\$02	May have two chips, two /CS lines, active low. May require 18kHz clock Superset of KS0108
S1D133xx SED133x	\$06	Select 6800 bus mode on the module
T6963	\$0A	May have a Font select line
LC7981 HD61830	\$16	

# IO-Warrior56

## 5.10.3 SPI Special mode function

IO-Warrior56 has a hardware SPI interface enabling it to talk to many peripheral devices. IOW56 supports SPI master mode.

To enable the SPI function a report with ID 8 is sent to interface1:

ReportID	1	2	3	4	...	62	63
\$08 out	enable	mode	clock	\$00	\$00	\$00	\$00

"enable" = \$00 disables the SPI and \$01 enables it.  
 "mode" contains flags specifying the operating mode for the SPI:

- 7 - LSBfirst
- 6 - unused, write zero
- 5 - unused, write zero
- 4 - unused, write zero
- 3 - unused, write zero
- 2 - CPHA
- 1 - CPOL
- 0 - unused, write zero

"LSBfirst" selects which bit of the data byte gets shifted first. "LSBfirst" = 0 shifts MSB first, "LSBfirst" = 1 shifts LSB first.

"CPHA" works together with "CPOL" to specify which clock edges are used to drive and sample data bits.

"CPOL" = 0 causes SCK to idle low between data bytes, "CPOL" = 1 makes SCK idle high.

"CPHA" = 0 causes data to be sampled on the first clock edge and driven on the second edge. "CPHA" = 1 causes data to be driven on the first edge and sampled on the second edge (this is the opposite behaviour of IOW24 CPHA bit).

Enabling SPI takes P5.0..P5.4 out of the control of interface zero.

clock sets the clock divider. The master clock rate is 24 MHz which is divided by clock+1. The valid range for clock is 1 to 255. So the fastest SCLK rate is 12MHz, the slowest 93.75kHz.

SPI does always shift data in and out simultaneously. So there is only one command to send data out of SPI that does also result in the same number of bytes being read in and returned to the host. If the intention is to only read data from an external device it is still necessary to shift out the same number of dummy bytes to that device.

Data transfers on the SPI are initiated by a report with ID 9:

ReportID	1	2	3	4	...	62	63
\$09 out	count	flags	data	data	data	data	data

"flags" contains the following bits:

- 7 - useDRDY, 1 = do handshake
- 6 - SSactive, 1 = /SS stays active
- 5 - ignoreDRDY, 1 = first byte ignores /DRDY
- 4 - unused, zero
- 3 - unused, zero
- 2 - unused, zero
- 1 - unused, zero
- 0 - unused, zero

"useDRDY" enables a handshaking signal that allows the slave to signal if and when it is ready to accept or send data.

If "useDRDY" = 1 IO-Warrior will check for the /DRDY signal to be low before it starts shifting a data byte. If the slave wants to pause the data transmission it has to pull /DRDY high before the end of the current byte transfer.

Upon starting a data transfer it may be desired to send the first byte without the slave signalling /DRDY low. By setting "ignoreDRDY" to 1 the first byte of this report is sent to the slave without checking /DRDY. Prior to shifting the next byte IO-Warrior will check the status of /DRDY.

"count" has the number of bytes to shift, values 1-61 are valid, others will be ignored.

IO-Warrior asserts /SS before starting to shift the first data byte of this report and will deassert it after completing the last byte, unless bit 6 "SSactive" is = 1. If "SSactive" is set /SS will stay asserted after the last byte of the report has been transferred, allowing more than 61 bytes to take part of a single transfer.

Data shifted in by IO-Warrior during a transaction is returned in a report with ID 9:

ReportID	1	2	3	4	...	62	63
\$09 in	count	data	data	data	data	data	\$00

"count" holds the number of valid bytes in the report.

# IO-Warrior56

## 5.10.4 Driving a LED matrix

IO-Warrior56 has the capability to drive a matrix of up to 8x64 LEDs with the aid of a few simple external driver chips.

To enable the receiver function a report with ID \$14 is sent to interface 1:

ReportID	1	2	3	4	...	62	63
\$14 out	enable	\$00	\$00	\$00	\$00	\$00	\$00

enable = \$01 enables the LED function, enable = \$00 disables it again.

Data to be displayed in the matrix is written in two blocks of 32 bytes:

ReportID	1	2	...	33	34	...	63
\$15 out	block	data0	data1	data31	\$00	\$00	\$00

"block" = 0 writes to the first four lines, "block" = 1 to the second four lines.

## 5.10.5 Switch Matrix Mode

IO-Warrior 56 can handle a matrix of 8x8 switches or keys. Other than with a keyboard controller it is possible to read out all possible combinations of closed switches. Since the switch status is reported as a bitmap there is no limitation to the number of switches that can be closed at the same time (diodes are required in the matrix though).

To enable the switch matrix function a report with ID \$18 is sent to interface 1:

ReportID	1	2	3	4	...	62	63
\$18 out	enable	\$00	\$00	\$00	\$00	\$00	\$00

"enable" = \$01 enables the switch matrix function, "enable" = \$00 disables it again.

The status of the matrix is returned when ever there is a change of status or it can be requested immediately by sending a report with ID \$19:

ReportID	1	2	3	4	...	62	63
\$19 out	\$00	\$00	\$00	\$00	\$00	\$00	\$00

The status of the matrix is returned in an input report with ID \$19. A set bit denotes a closed switch:

ReportID	1	2	3	4	5	6	7	8	...	63
\$19 in	Y0	Y1	Y2	Y3	Y4	Y5	Y6	Y7	\$00	\$00

## 5.10.8 Getting current pin status

Due to the way Windows implements HID support IO-Warrior is unable to continuously send its status. HID class devices do have a function that allows the host to set the rate at which reports should be repeated if there is no change to the data. Windows does set this rate to zero for IO-Warrior, which means IO-Warrior may send data only if there are changes.

To be able to get the current status from IO-Warrior it does support a Special Mode Function that always returns the current status of all pins.

To get the port status just send a report with ID \$FF to interface 1:

ReportID	1	2	3	4	...	62	63
\$FF out	\$00	\$00	\$00	\$00	\$00	\$00	\$00

This will result in the current pin status to be returned immediately in an input report with ID \$FF with the following format:

ReportID	1	2	3	4	5	6	7	...
\$FF in	Prt0	Prt1	Prt2	Prt3	Prt4	Prt5	Prt6	\$00

# IO-Warrior56

## 6. Absolute Maximum Ratings

Storage Temperature .....	-55°C to +100°C
Ambient Temperature with power applied.....	-40°C to +85°C
Ambient Temperature using USB .....	-10°C to +85°C
Supply voltage on Vcc relative to Gnd .....	-0.5V to +6V
DC input voltage.....	Gnd-0.5V to Vcc+0.5V
Maximum current into any port pin.....	-25/+50mA
Maximum combined output low current for all port pins .....	150mA
Static discharge voltage.....	>2000V
Latch-up current .....	200mA

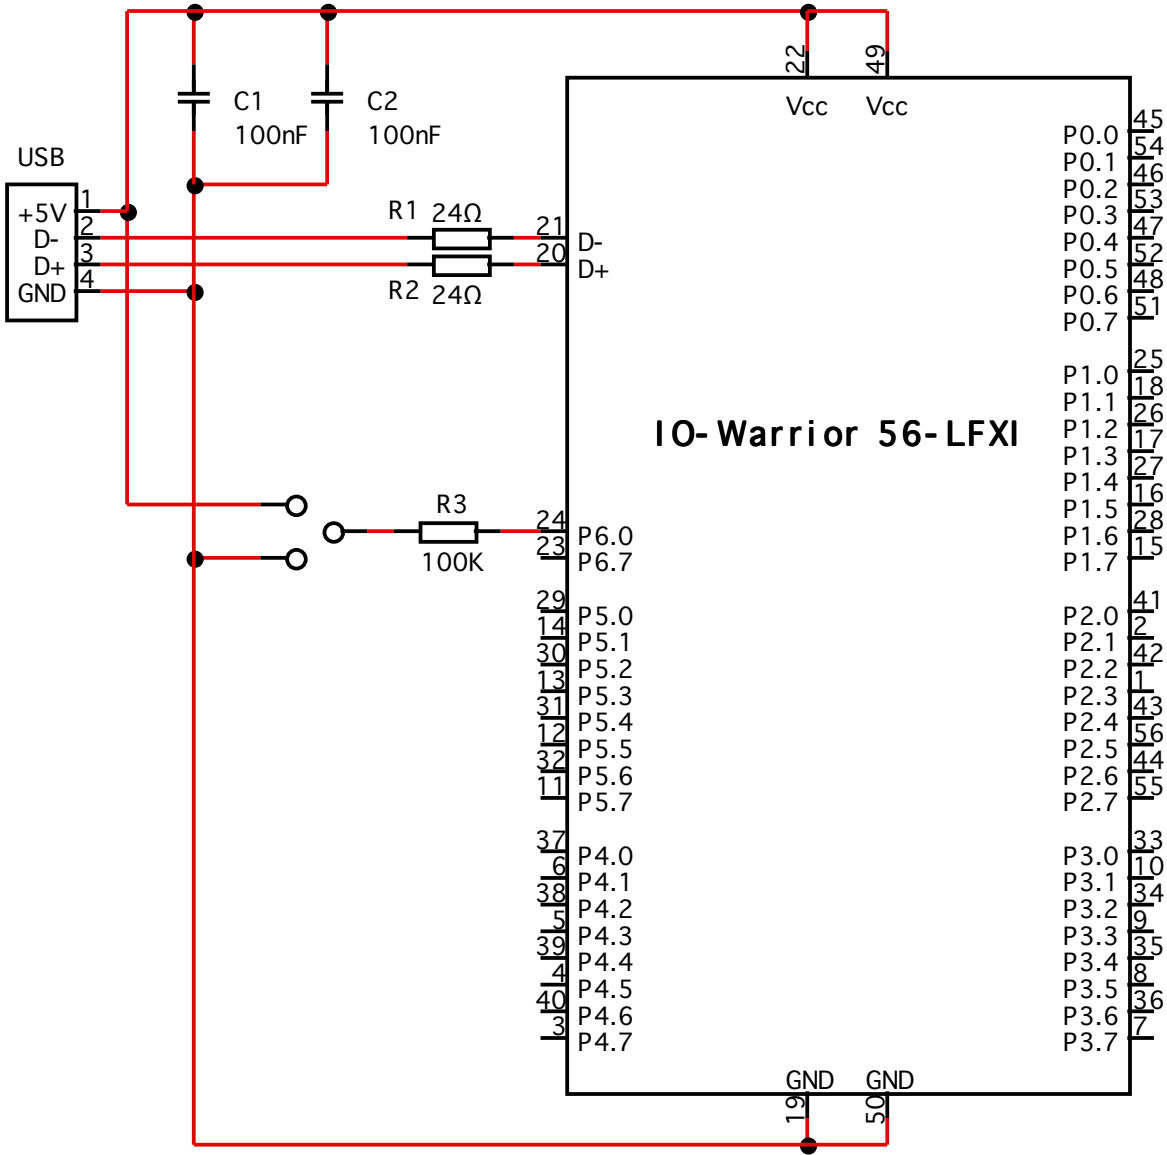

### 6.1 DC Characteristics

	Parameter	Min	Max	Units	Remarks
V <sub>cc</sub>	Operating Voltage	4.35	5.25	V	
I <sub>cc</sub>	Operating Supply Current		50	mA	Depending on operating mode
I <sub>sb</sub>	Suspend mode current		25	μA	Oscillator off
I <sub>ol</sub>	Sink current on output pins		25	mA	V <sub>out</sub> = 0.75V
R <sub>up</sub>	Pull-up Resistance	4	8	kΩ	
V <sub>ith</sub>	Input threshold voltage	45%	65%	V <sub>cc</sub>	All ports, low to high edge
V <sub>H</sub>	Input hysteresis voltage	6%	12%	V <sub>cc</sub>	
	<b>USB Interface</b>				
V <sub>oh</sub>	Static output high	2.8	3.6	V	15kΩ±5% to GND
V <sub>ol</sub>	Static output low		0.3	V	
V <sub>di</sub>	Differential Input sensitivity	0.2		V	(D+)-(D-)
V <sub>cm</sub>	Differential Input common Mode Range	0.8	2.5	V	
V <sub>se</sub>	Single Ended Transceiver Threshold	0.8	2.0	V	
C <sub>in</sub>	Transceiver capacitance		20	pF	
R <sub>ext</sub>	External USB series resistor	23	25	Ω	In series with each USB pin
Z <sub>o</sub>	USB driver output impedance	28	44	Ω	Including R <sub>ext</sub>
V <sub>Ccrs</sub>	D+/D- crossover voltage	1.3	2.0	V

## 10. ESD Considerations

IO-Warrior has an internal ESD protection to withstand discharges of more than 2000V without permanent damage. However ESD may disrupt normal operation of the chip and cause it to exhibit erratic behaviour.

For the typical office environment the 2000V protection is normally sufficient. Though for industrial use additional measures may be necessary.

When adding ESD protection to the signals special care must be taken on the USB signal lines. The USB has very low tolerance for additional resistance or capacitance introduced on the USB differential signals.

In any case the USB 2.0 specification chapter 6 and 7 should be read for detailed specification of the electrical properties.

## 10.1 EMC Considerations

IO-Warrior uses relatively low power levels and so it causes few EMC problems. The most important issue is to provide a very clean layout for the power supply. IO-Warrior56 runs at 24MHz internal clock rate, this can cause current spikes if the supply lines are not carefully laid out.

To avoid any EMC problems the following rules should be followed:

- Keep the PCB traces from the resonator to the chip pins as short as possible.
- Put the 100nF ceramic capacitors right next to the power supply pins of the chip and make sure the PCB traces between the chips power pins and the capacitor are as short as possible.
- Run the power supply lines first to the capacitor, then to the chip.
- Connect the second ground and supply pin in the shortest possible way to the first ground and supply pin. No other things may have precedence over this.
- Keep the two USB signal lines close to each other, route no other signal between them. USB uses differential signalling so the best signal quality with lowest RF emission is achieved by putting these lines very close to each other.

## 11. Revision History

IO-Warrior 56 does not use the same code base as IO-Warrior24 and IO-Warrior40, so the version numbers are not identical.

### 1.0.0.1

Initial release

### 1.0.0.0

Not released due to a bug.
